

PRISM

TAKE HOME ASSESSMENT

We would like you to support Prism's technical development during this period. The role combines technical ownership, coordination with our external product partners, and hands-on work on Prism's LLM and quantitative intelligence systems.

Responsibilities

- **Technical coordination and architecture.** Serve as Prism's primary technical point of contact for the outsourced full-stack developer and UI/UX designer. Translate product requirements into technical decisions, clarify interfaces between the frontend, backend, data systems, and LLM layer, and resolve implementation questions before they delay delivery.
- **Review and handoff.** Review external deliverables for compatibility with Prism's architecture and make sure the team receives usable code, documentation, environment instructions, data schemas, and API contracts. Track dependencies and blockers, and make sure ownership can move cleanly between external and internal contributors.
- **LLM development.** Build the LLM layer that lets users explore Prism's financial and alternative datasets in natural language. This includes connecting the model to the relevant data and tools, structuring prompts and outputs, surfacing sources and dates, and creating practical evaluations for factual accuracy, reproducibility, latency, and cost. Document important assumptions and failure cases.
- **Now casts and indices.** Develop transparent models that convert raw public and alternative data into now casts, indices, and other derived signals. Define the methodology, transformations, baselines, and weighting; test the output against historical data where appropriate; guard against look-ahead bias; and package the code, output data, and methodology so the product team can integrate and explain the result.

Short Trial Project

Before our next meeting, please complete the following small Prism-related project. It should take no more than two to three hours. The goal is to understand how you approach data, methodology, code structure, and communication rather than to produce a production-ready model.

Open Ended Prism Project

Choose any small project that is relevant to Prism. It could be a prototype index or nowcast, a data-cleaning or quality-check workflow, an LLM tool or evaluation, a market-intelligence signal, or another focused feature that you believe would be useful to the product.

1. **Define the problem.** Briefly explain what you are building, who it would help, and why it is relevant to Prism.
2. **Build a working prototype.** Keep the scope small enough to finish within the time limit. Use public, sample, or synthetic data as appropriate, and make your assumptions clear.
3. **Present the result.** Provide the most useful output for the project, such as a chart, table, score, short demo, or sample response.
4. **Document the work.** Submit the code or notebook with a brief README covering the approach, assumptions, limitations, and what you would improve before production use.
